## 内容概要

The problems in this book are intended to cover the topics in an average second- and third-year undergraduate course in Quantum Mechanics. After a preliminary chapter on orders of magnitude, there are eight chapters on topics arranged in a fairly conventional order. The tenth and final chapter contains a selection of miscellaneous problems on the topics of the previous chapters. I have separated them from the others on the grounds of their being somewhat longer and perhaps more difficult. But you should not be deterred from trying them on that account.

书籍目录

Acknowledgements Preface for the reader 1 Numerical values Values of physical constants Problems Solutions 2  
Fundamentals Summary of theory Problems Solutions 3 Schrodinger equation Summary of  
theory Problems Solutions 4 Orbital angular momentum, hydrogen atom, harmonic oscillator Summary of  
theory Problems Solutions 5 Matrices, spin, addition of angular momentum Summary of theory Problems Solutions 6  
Approximation methods. Time-independent perturbation theory, variational method Summary of  
theory Problems Solutions 7 Identical particles, multielectron atoms Summary of theory Problems Solutions 8  
Time, time-dependent perturbation theory, transitions Summary of theory Problems Solutions 9  
Scattering, reactions Summary of theory Problems Solutions 10 Miscellaneous Problems Solutions References Index
