章节摘录

插图 : Computers enable film-makers to achieve imagery that other forms of special effects can't. They can put actors of today into old films so that they look as though they were part of the original scene. They can copy small crowds of moving people and repeat them to make one huge crowd. Monsters and dinosaurs have never looked so frightening and real. Even babies and animals can look as though they are talking to each other. Let's take the talking baby as an example of how computers are used to produce special effects. The audience sees a baby girl sitting up in a cot, looking up at her favourite toy. The baby is obviously too young to talk. Suddenly, she opens her mouth and starts speaking fluently to the toy. The talking baby doesn't look fake. She looks completely real. How is this done? First, the film-makers film a baby sitting up in a playpen. They get the baby to look up to where the toy would be. Next, the film-makers film a young girl talking. She is asked to say the words the baby will say and to move her head as the baby moved her head. The child's whole face isn't filmed - just her mouth. These two pieces of film will be combined in the computer. After the film is developed, it is put into a computer using a process called digitising. This turns the frames of the film into frames on the computer. The computer operator then replaces the baby's lips with the child's lips. It is similar to using scissors to cut lips from one photo and paste them onto another.
